Funding Grants: Identification of hESC-mediated molecular mechanism that positively regulates the regenerative capacity of post-natal tissues

Public Summary:

This work describes techniques, which one can use for isolating muscle stem cells and understanding their regenerative properties.

Scientific Abstract:

In our studies of muscle regeneration we have developed, modified, and optimized techniques to isolate and study the stem and precursor cells to muscle tissue. Our goals have been to obtain for study muscle fibers in bulk, or the fiber-associated cells, separately from the other cells found in muscle. Using these techniques, myofiber-associated cells may be isolated from neonatal through adult muscle, from resting or from regenerating muscle, thus allowing one to investigate the cellular populations participating during the time course of these events. The protocol is applicable to any age and condition of muscle and may be adapted for other tissues.
